EARTH LAYERS DRAWING LAB

/2I

INTRODUCTION: Scientists who study the earth's layers are called geologists. Since they cannot see the inside of the earth, they use geographical dues to help them. These dues are gathered from activities such as volcanoes and earthquakes. From these clues, geologists make inferences about what the inside of the earth actually looks like.

HR

Geologists believe the earth is a made up of different layers known as the crust, mantle, inner core, and outer core. These layers vary in depth, pressure, and temperature. Since pressure and temperature affect density, each layer has a different density as well. The density of each layer determines its position in the earth.

EARTH LAYER	DENSITY	
Crust	2.6 g/cm ³	
Mantle	4.0 g/cm ³	
Outer Core	10.2 g/cm ³	
Inner Core	13.1 g/cm ³	

ANALYSIS:

- 1. What layer of Earth is least dense? ______
- What layer of Earth is most dense? _____
- 3. What is the relationship between the density and position of each Earth layer?
- 4. If you were to make a model of Earth using the materials listed below, what should you use to represent

the crust? ______ the inner core? ______

MATERIAL	DENSITY
Clay	2.0 g/cm ³
A marble	2.4 g/cm ³
Aluminum foil	1.2 g/cm ³

MODELS: A model is a tool used by scientists to represent another object that is either too large or too small to study on its own. For instance, since atoms are too small to see, scientists use models to illustrate the structure of each atomic part. Similarly, since the Earth is so large, scientists construct models to represent the Earth on a much smaller scale. In this activity, you will create a model of Earth that is 22.2 million times smaller than the actual earth.

PROCEDURE:

1] Use a calculator to determine the depth (in cm) each layer should be on your slice of the Earth. Record your data in the table below.

EARTH LAYER	ACTUAL THICKNESS	SCALE MULTIPLIER	THICKNESS ON MODEL (in cm)
Crust	30 km	.00385 cm/km	
Mantle	2890 km	.00385 cm/km	
Outer Core	2260 km	.00385 cm/km	
Inner Core	1220 km	.00385 cm/km	

2] Use a ruler to mark off the location of each layer on your slice

- 3] Use a pencil to label each layer of earth on your slice
- 4] Color your slice according to the following key:
 - Crust-brown a.
 - Mantle- yellow b.
 - c. Outer Core- orange
 - d. Inner Core- red

CONCLUSION

The Earth is made out of layers that separate according to their . the density of each layer is affected by the of the material and the amount of it is under. The thinnest and least dense layer is known as the _____. The layer under the most pressure is known as the . Such high amounts of pressure cause this layer to remain in a state of matter even though the nickel and iron are at such a high temperature it should be melted. On the other hand, the outer core remains in a ______ state of matter even though it is made out of the same material as the inner core since there is not enough to change it to a solid.
